**HAZARDS**CRC

# SCENARIO PROJECT: using realistic disaster scenario analysis to understand natural hazard impacts and emergency management requirements

An Australian Government Initiative

THE UNIVERSITY  
OF QUEENSLAND  
AUSTRALIA

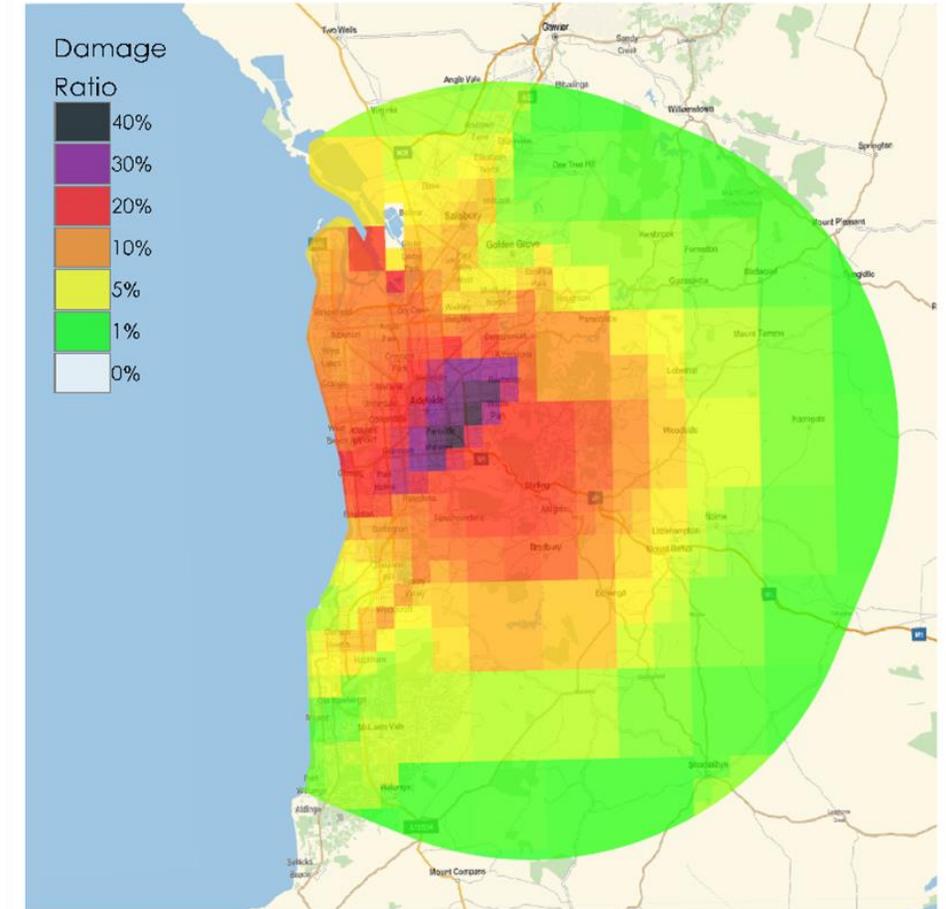

# Project objectives

- Develop a set of realistic disaster scenarios:
  - Quantify hazard magnitude and risk thresholds
  - Assess vulnerability and exposure at risk
- Use this framework to:
  - help communicate about extreme disaster risk
  - assess capability from emergency management sector

# Year 1: EQ scenario

- **Mw 6** earthquake on the Para fault, near **Adelaide**.
- Estimated recurrence interval: **1000 Years**.
- Modelled:
  - **hazard** (ground shaking and liquefaction)
  - damage to the **built environment, casualties** and disruption of **essential facilities** and **utility networks**.

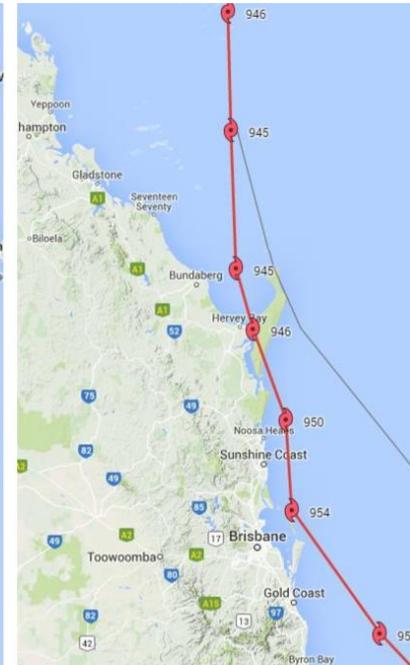

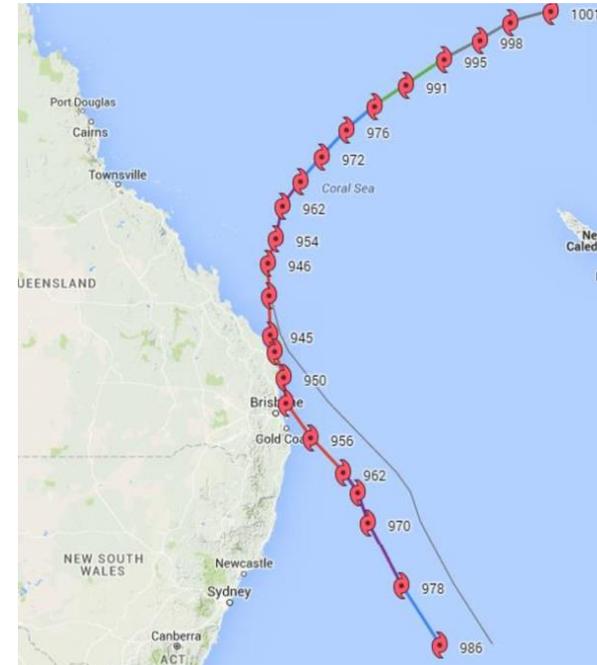

**Residential Damage** Percentage of Replacement Value of the local Buildings' Stock.

## Year 1: TC scenario

- **Cat 4 storm** impacting SE Queensland
- Focus on **wind hazard/damage**
- **> 500 year design** wind speeds for the region
- Worst impacted region was Harvey bay (including Fraser Island)
- **50 000 buildings** with moderate structural damage
  - Occupants may need to seek alternate shelter
- **8 000 buildings** with major structural damage
  - many needing complete rebuild
- The expected **wind induced loss is ~ \$12 Billion**

## Year 2: Melbourne EQ

- Focus on delivering a set of EQ events for Melbourne
- 3 sub-scenarios
- to be delivered by the end of this Financial Year

## Year 2 scenario: Heatwave risk in VIC/SA

- HW are responsible for *more deaths than all other natural perils in Australia put together* (Risk Frontiers, 2014)
- There is **no clear definition** of a HW event
- There is a pressing need for a common intensity metric
- BoM developed the **Excess Heat Factor** with this goal in mind
- Risk Frontiers has developed a **HW severity categories** based on EHF

# Excess Heat Factor

- The EHF metric takes into account:
  - the ability of the local community to adapt to its climate
  - the impact of sharp temperature spikes that do not allow such acclimatization
- A positive EHF indicates a heatwave
- The intensity of a HW event can be measured by the **peak EHF**
- By summing EHF values over the lifetime of an event we derive a measure of **Heat Load or accumulated EHF**

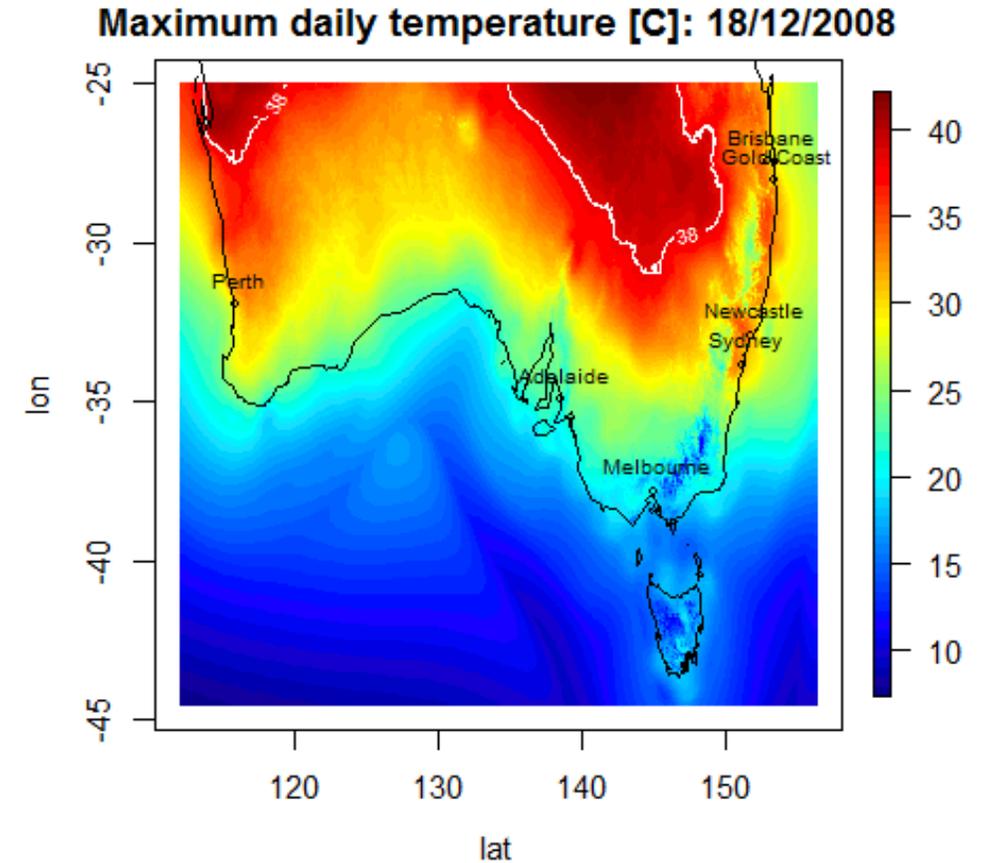

# Objectives

- 3 heatwave events for SE Australia (SA and VIC)
- Outcomes
  - Footprint of heat risk
  - Propose fatality HW severity classification system
  - Projection of fatalities
- Inform knowledge regarding overall **heat risk** to communities to improve **planning and risk management**

# Inputs

- 100 yr record of daily temperatures (max, min) (BoM)
- Peril Aus – Risk Frontiers’ fatality database
- Census data (ABS)

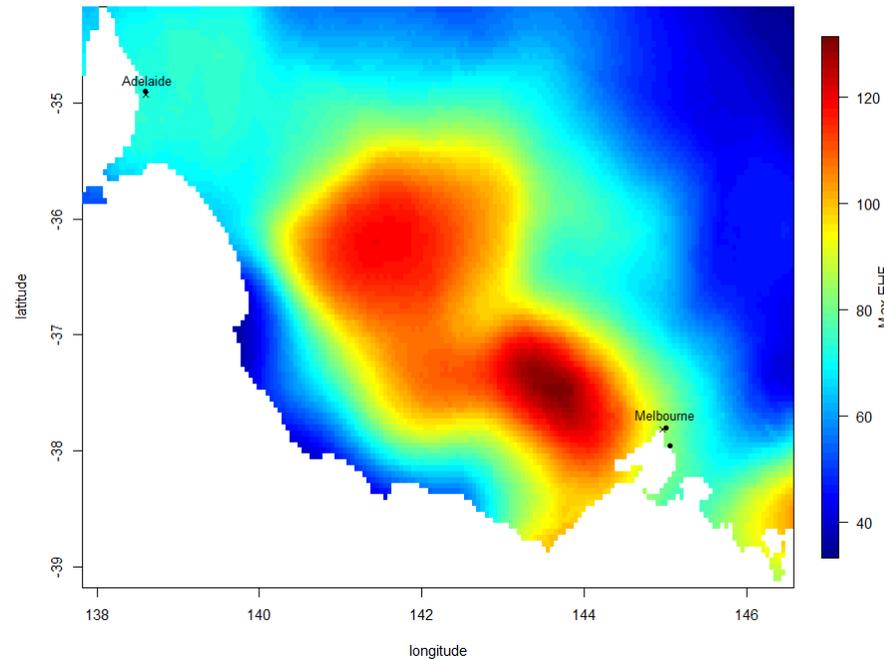

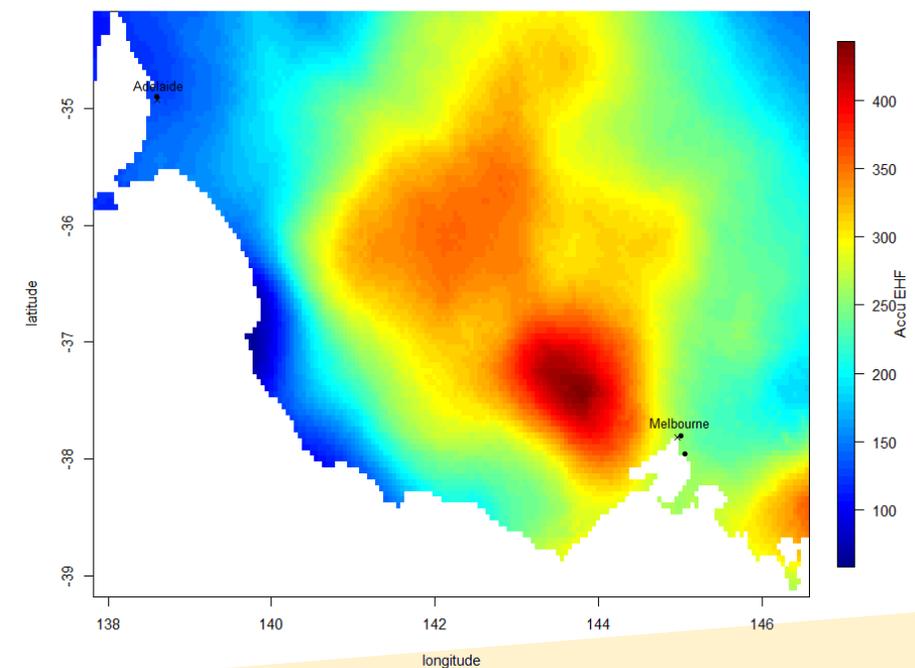

# Event definition

- An event starts when first grid cell in domain has **EHF > 0** for **3 consecutive days**
- Finishes when last cell turns back to EHF=0

Peak EHF over the event

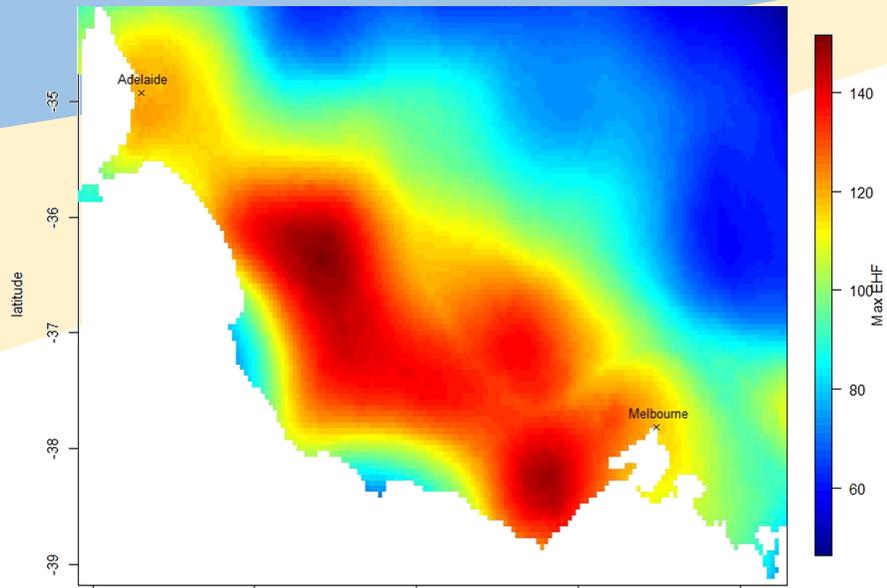

EHF accumulation over the event

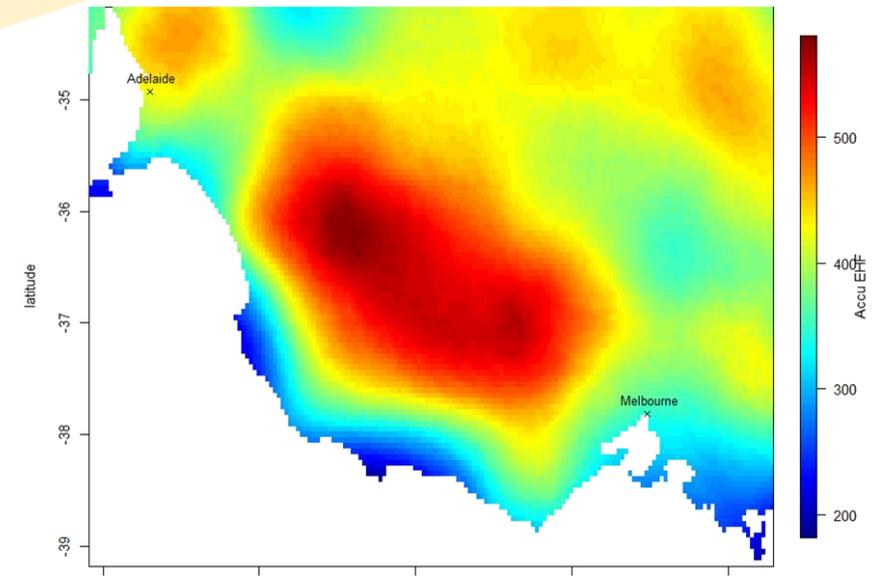

**JAN 1959**

**JAN 2009**

Peak EHF over the event

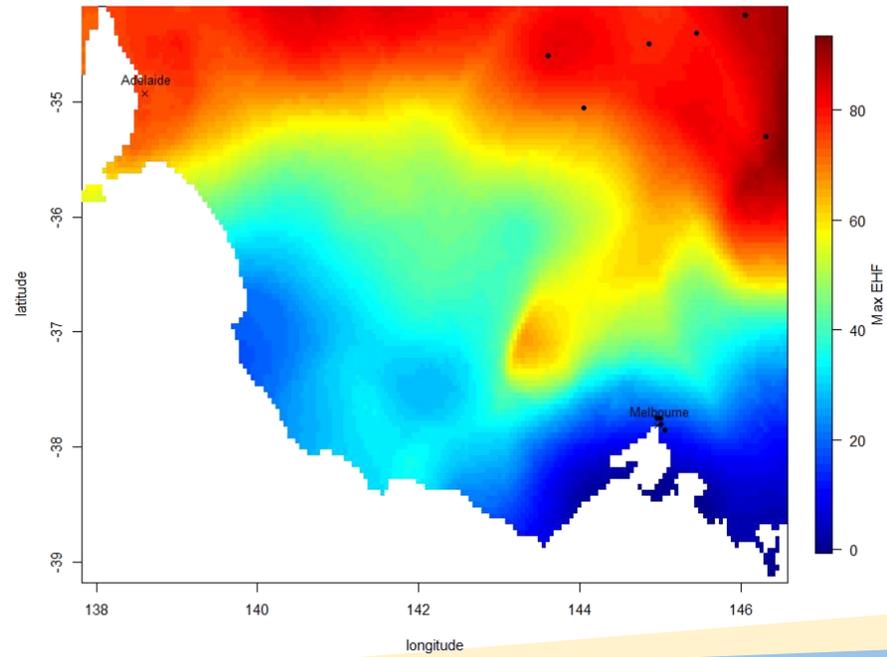

EHF accumulation over the event

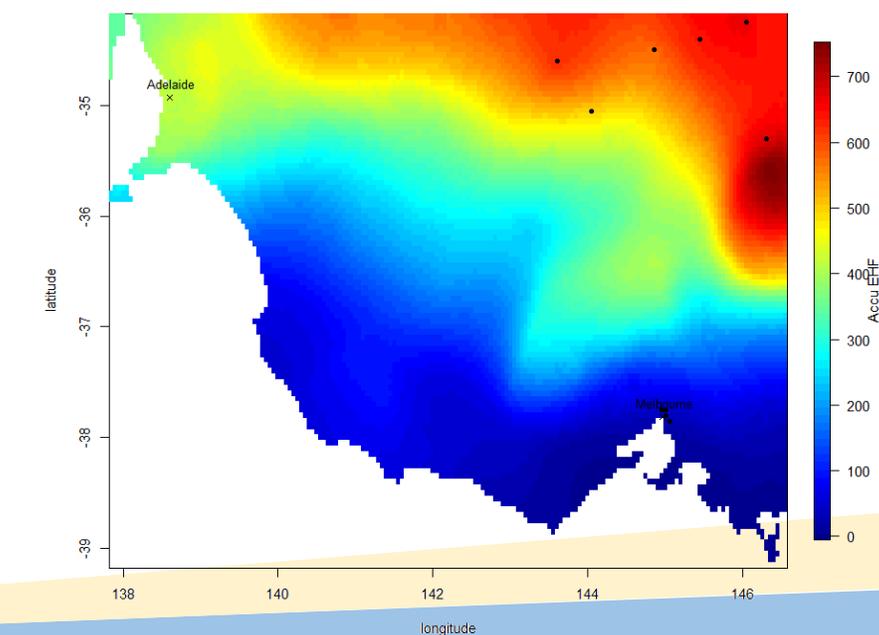

**JAN 1939**

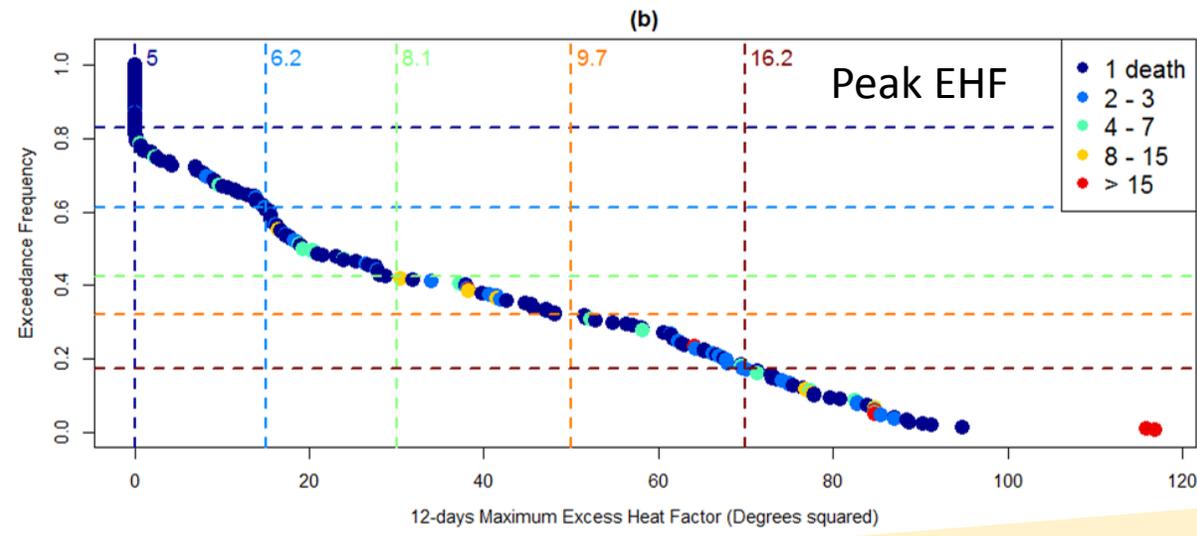

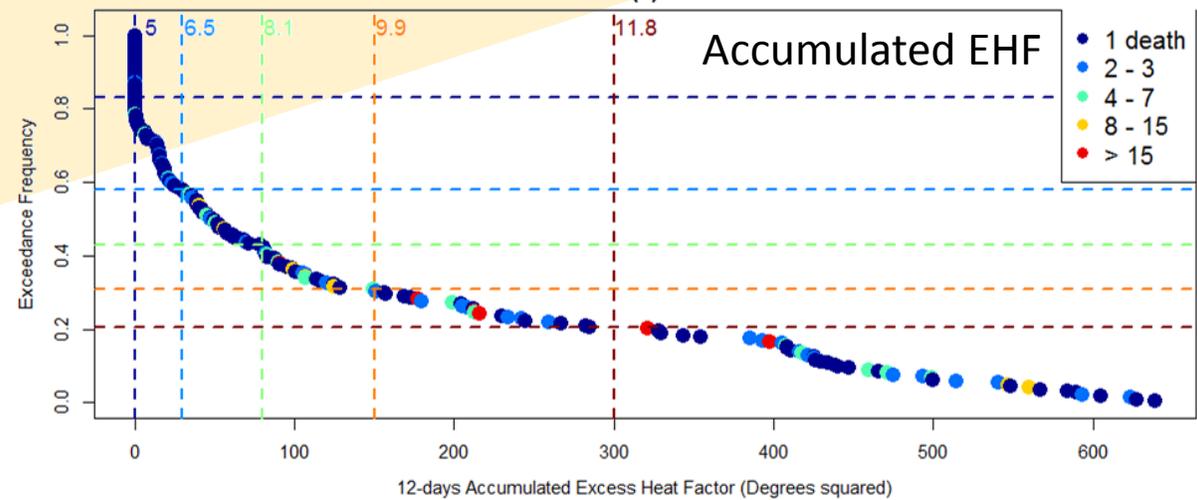

Peak EHF over the event

EHF accumulation over the event

# Heat Fatality risk categories

- Compute EHF for past century
- Match EHF data with fatality records from PerilAUS

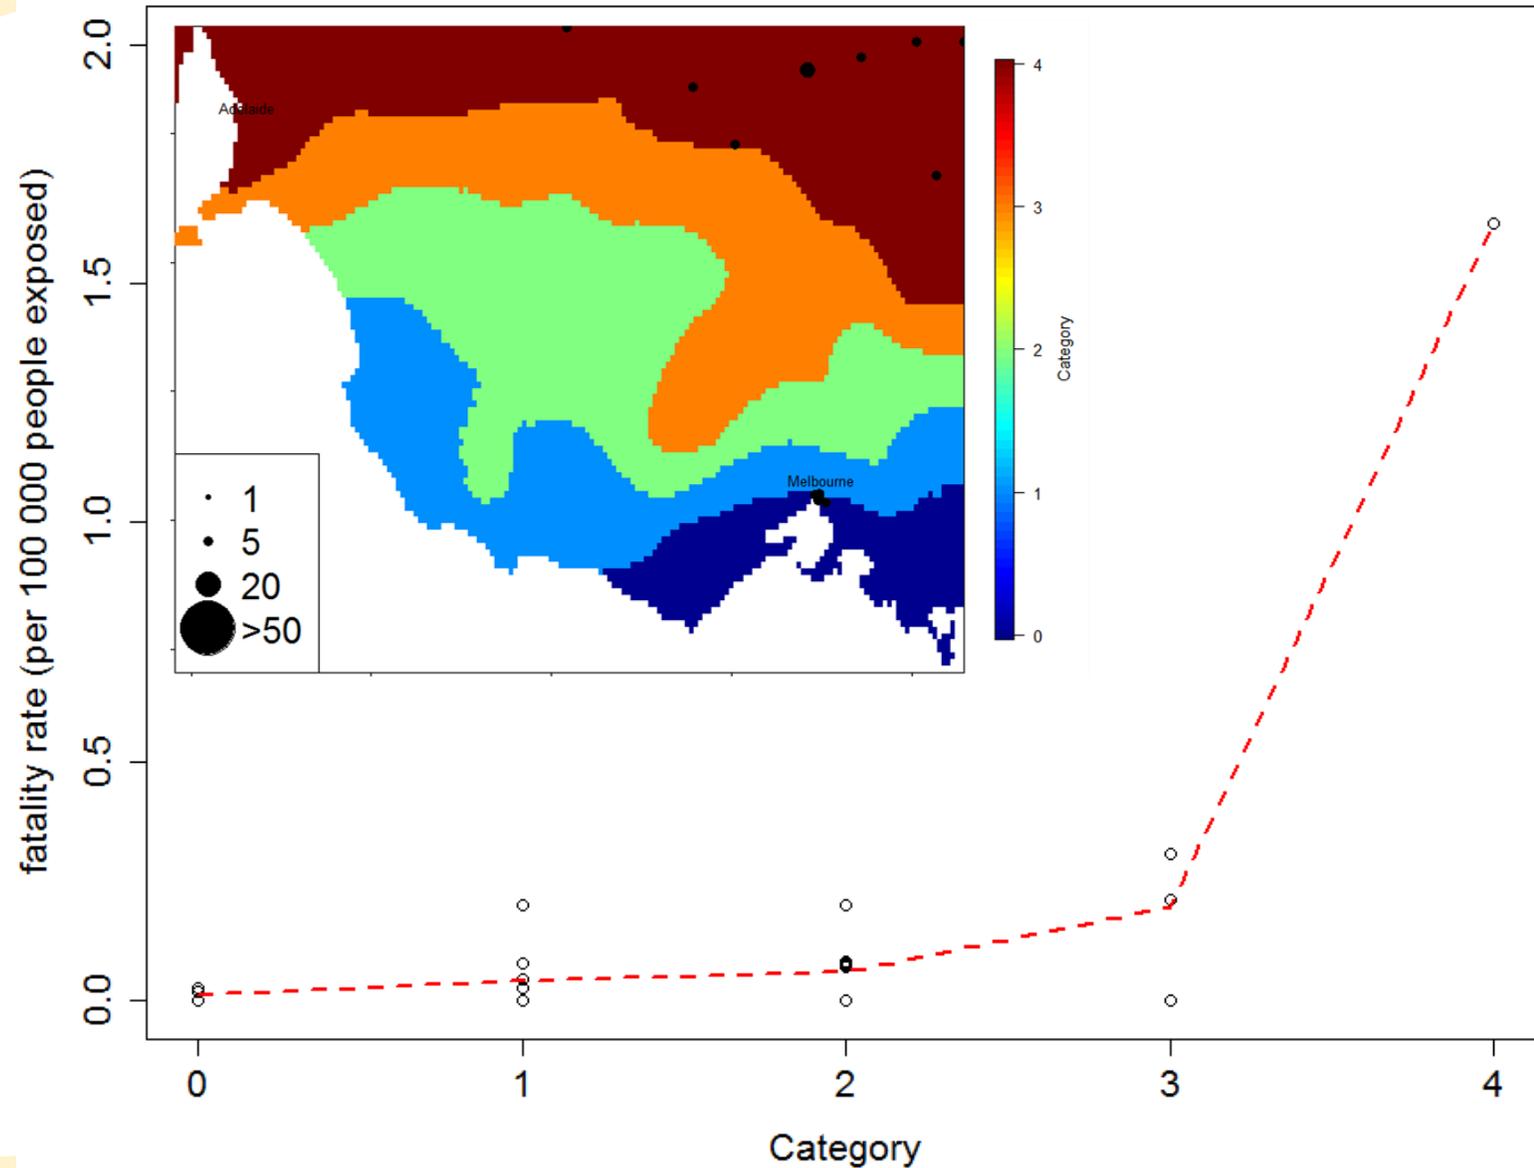

Category	EHF <sub>sum</sub>	EHF <sub>max</sub>	Mean number of fatalities	Percentage of record covered
CAT0	> 0	> 0	5	82.6
CAT1	> 30	> 15	6.7	55.4
CAT2	> 80	> 30	8.6	38.9
CAT3	> 150	> 50	10.4	28.6
CAT4	> 300	> 70	18.5	12

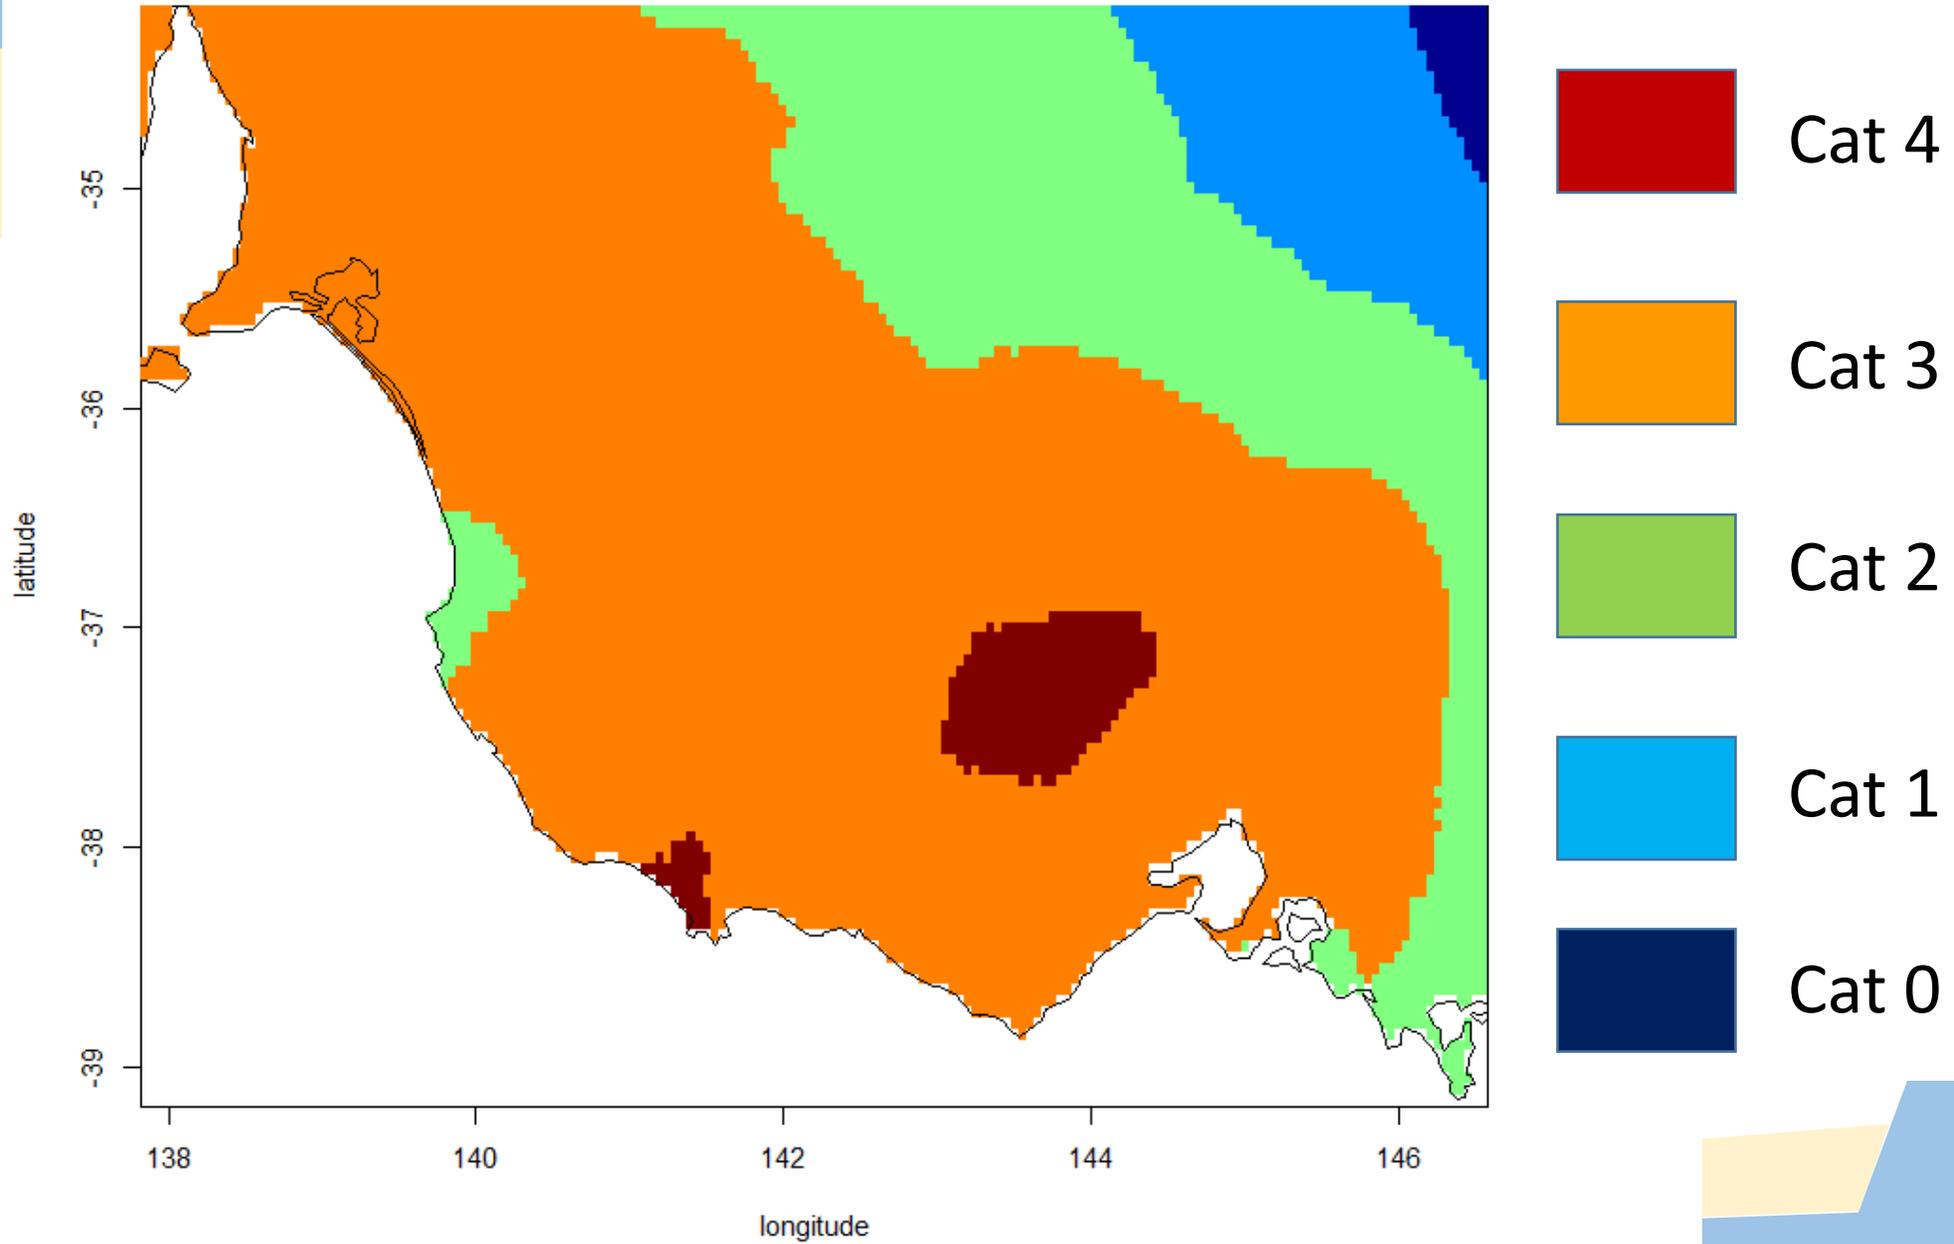

# Fatality projections

Vulnerability curve to enable projection of fatalities given EHF characteristics

- 10 biggest events of the last decade
- Census population records trended over the period
- Normalised heat-related fatality records

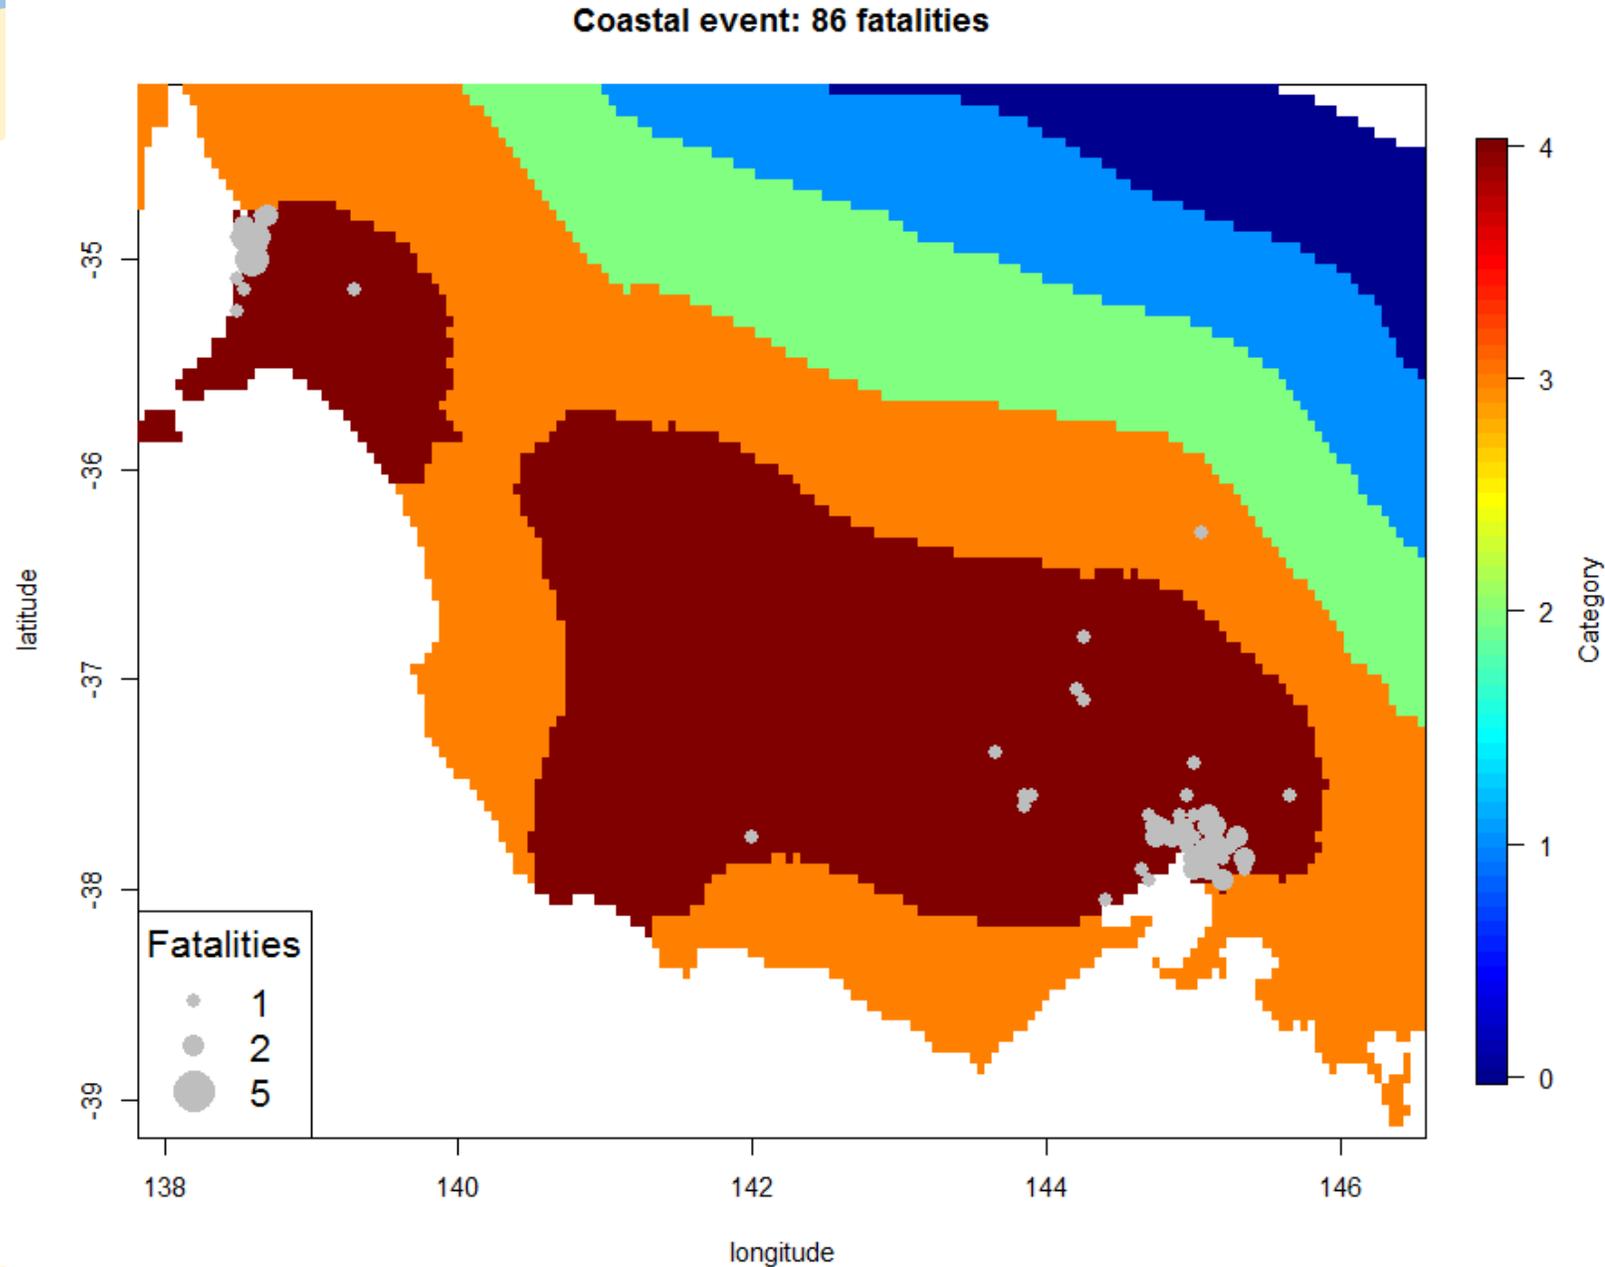

Event 3

## Scenario 1

- Coastal event impacting both Adelaide and Melbourne with Cat 4 HW
- 86 fatalities

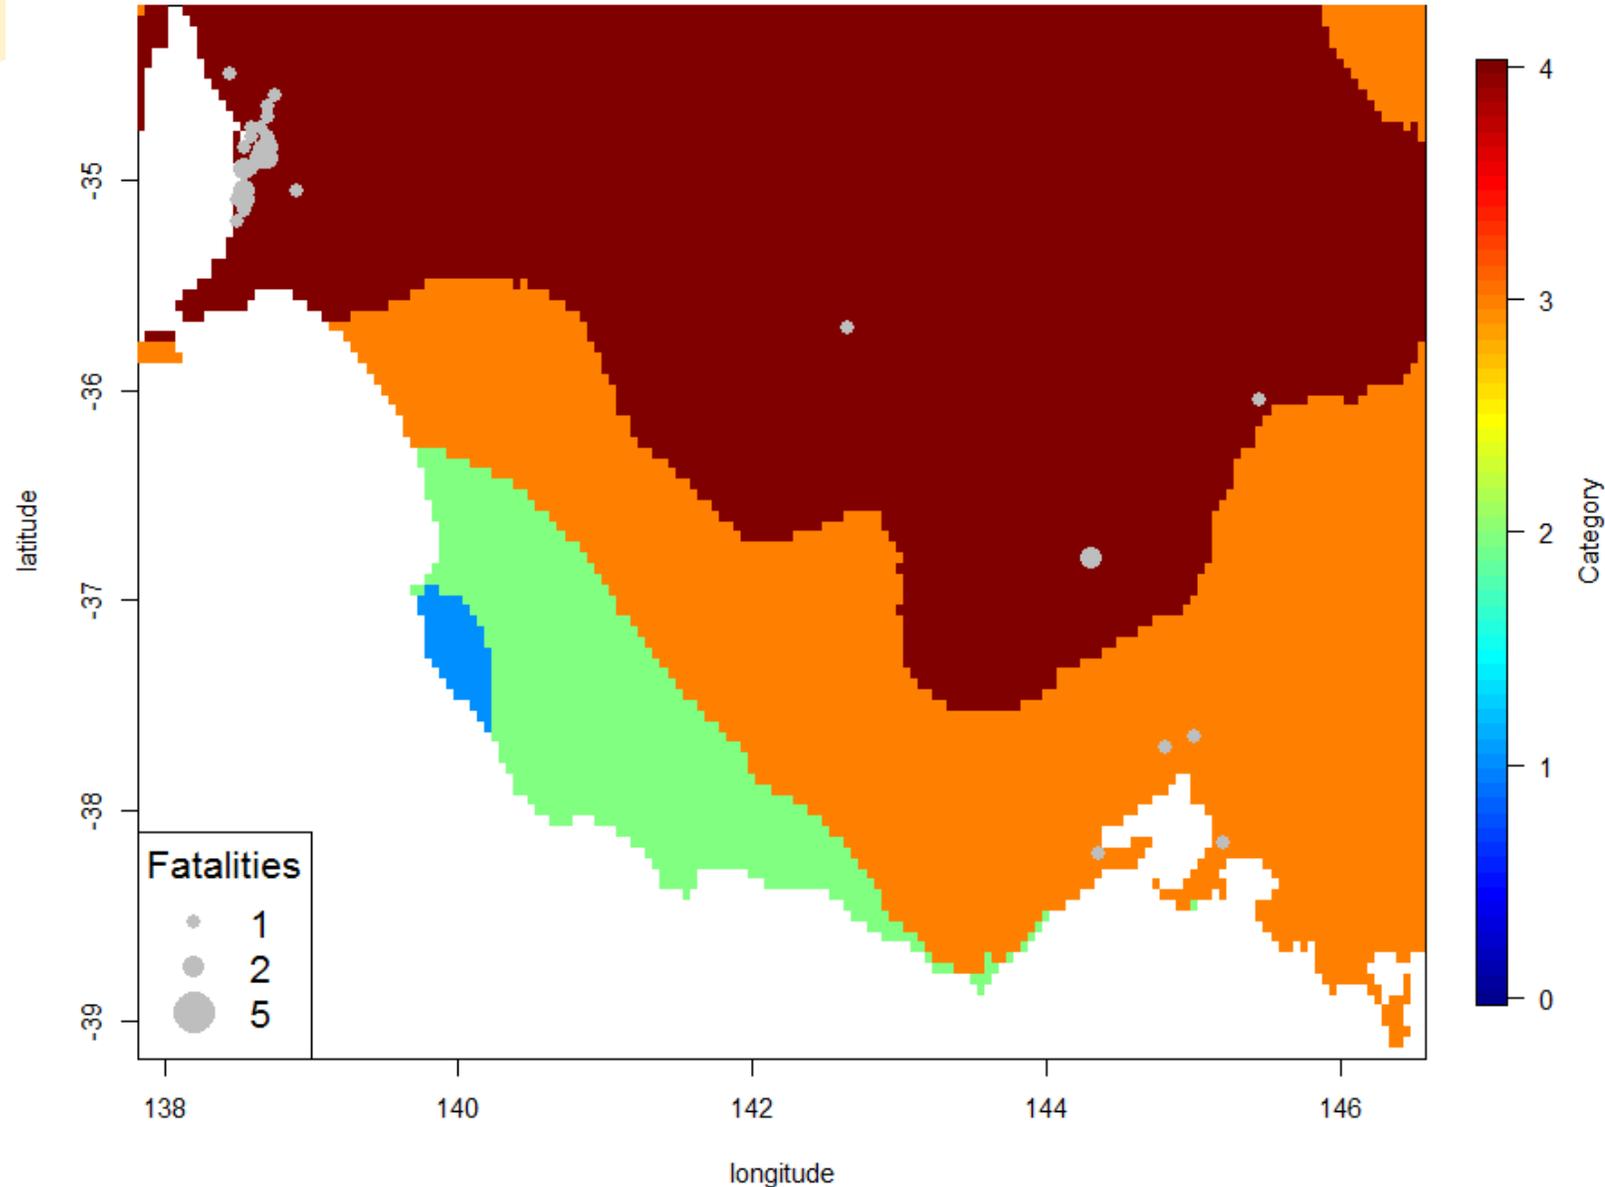

## Scenario 2

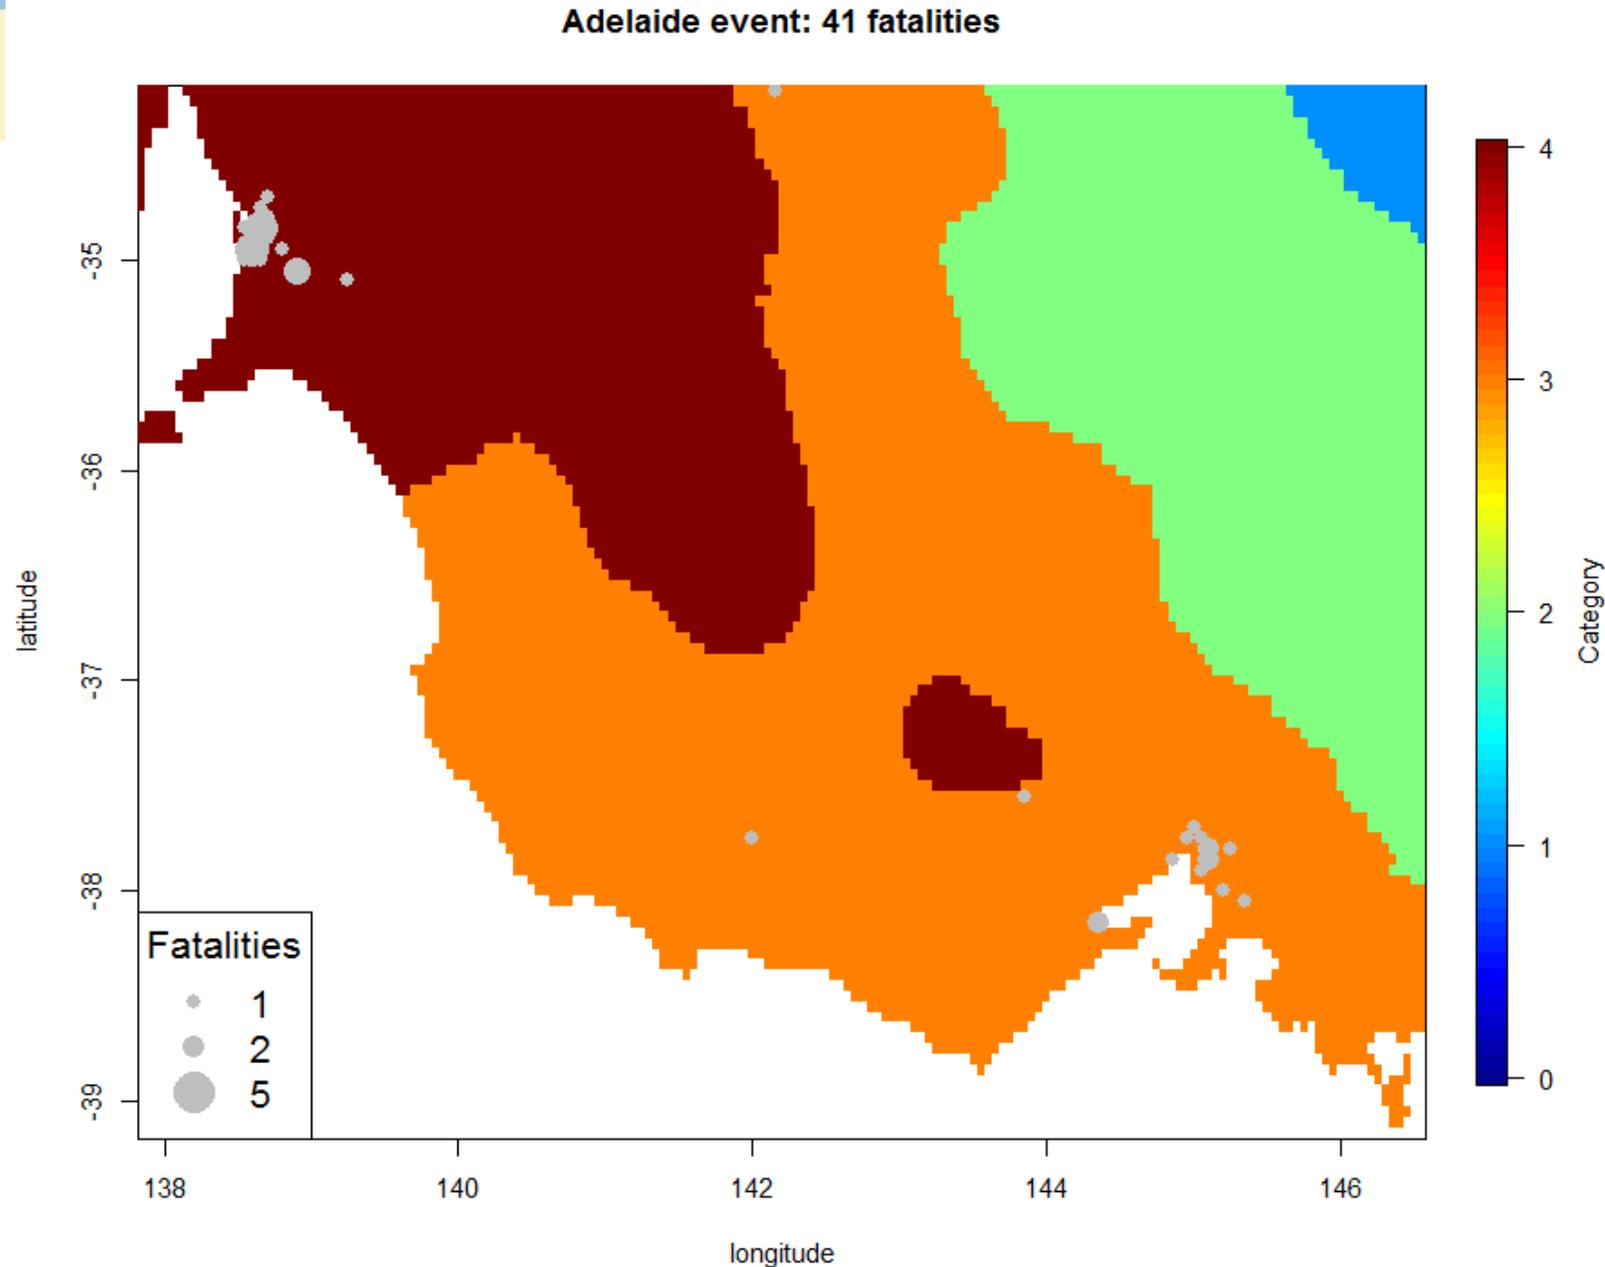

- Inland event
- Higher intensity overall hazard but impacting less populated regions
- Adelaide in cat 4 and Melbourne in cat 3 risk
- 35 fatalities

Inland event: 35 fatalities

## Scenario 3

- Most severe of the 3 scenarios in terms of hazard intensity
- Peak Cat 4 risk in Adelaide
- Melbourne in Cat 3 risk
- 41 fatalities

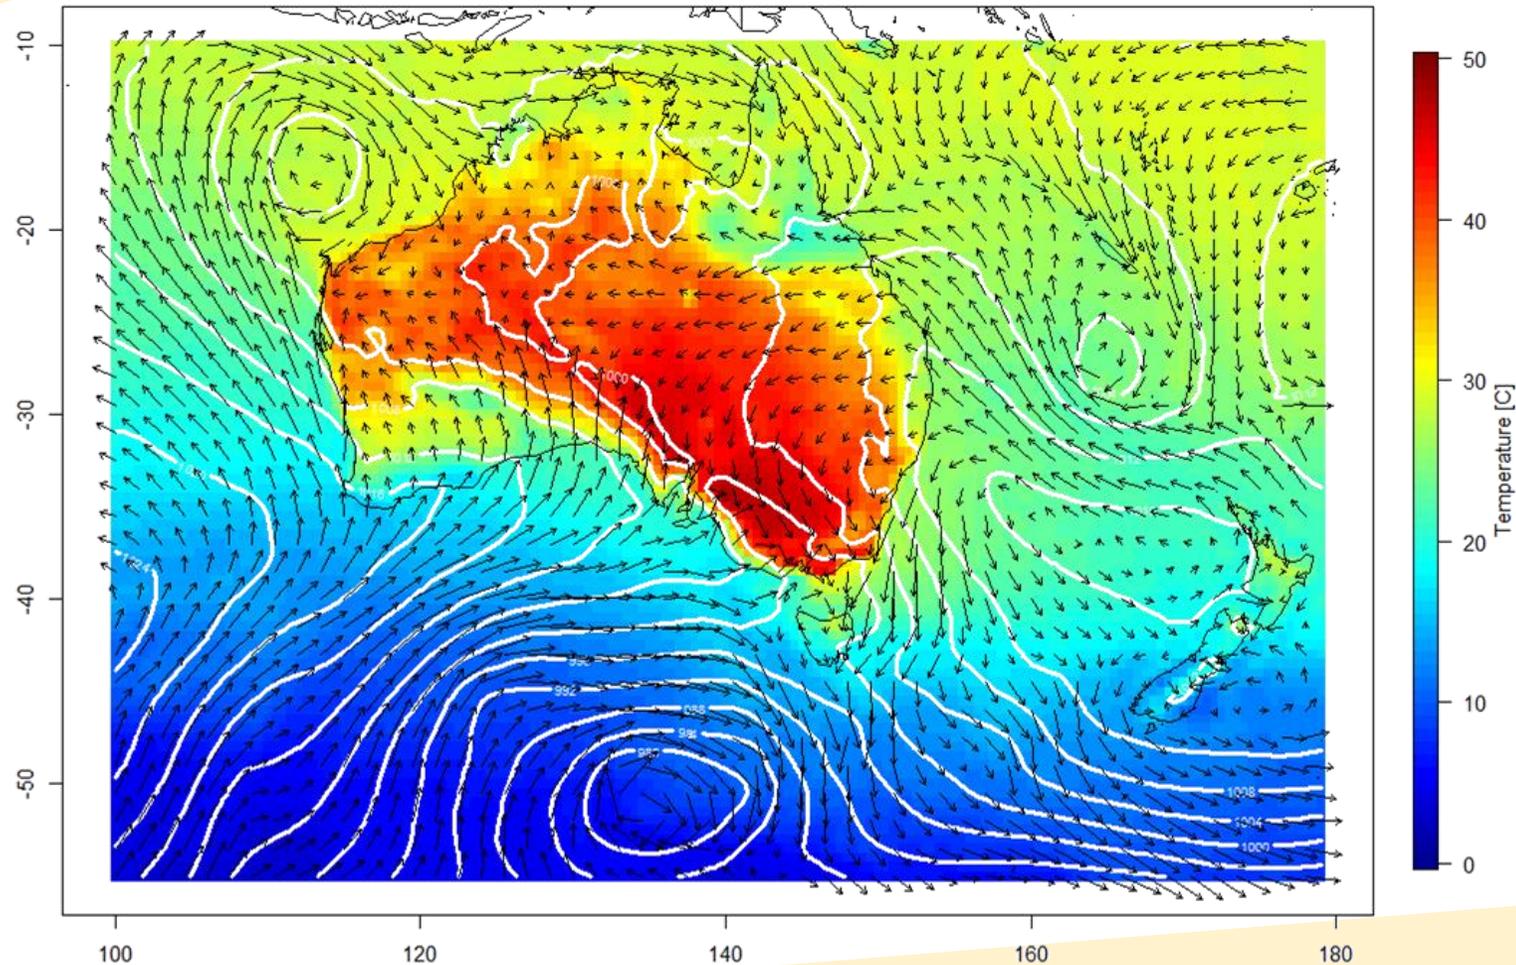

# End user utilisation / feedback

- SA EQ: Utilised in cost benefit analysis for SA Government.
- QLD TC: Utilised by AFAC / AGD to exercise disaster response analysis
- VIC EQ: To be utilised as basis for Melbourne Earthquake exercise
- HW:
  - Positive feedback from EMV (Lew Short)
  - Planning workshop with VIC agencies – health, ambulance etc.
  - Positive collaboration opportunities identified with BoM Heatwave Project Director
- General feedback that agencies are wanting to use scenarios as a basis for capability planning into the future and for forecasting impacts to improve public information and warnings
- Promotion of the project through Asia Pacific Fire Magazine and Fire Australia

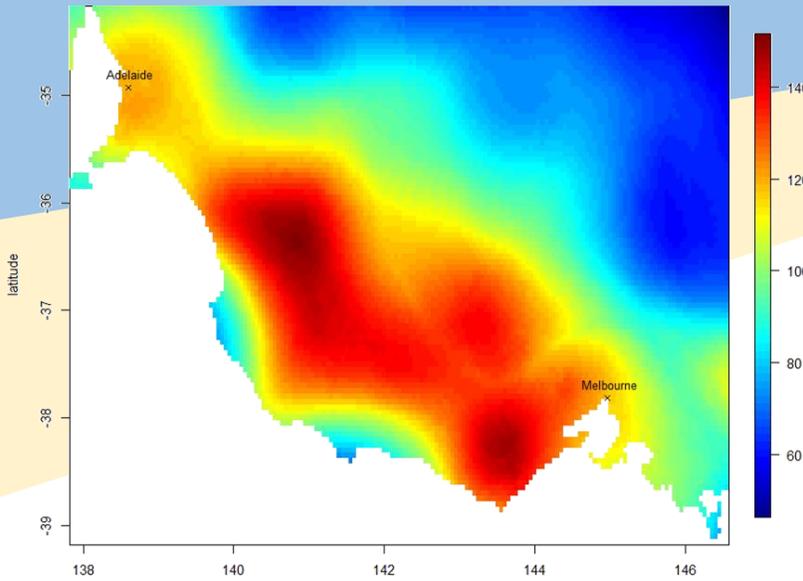

# Synoptic setting

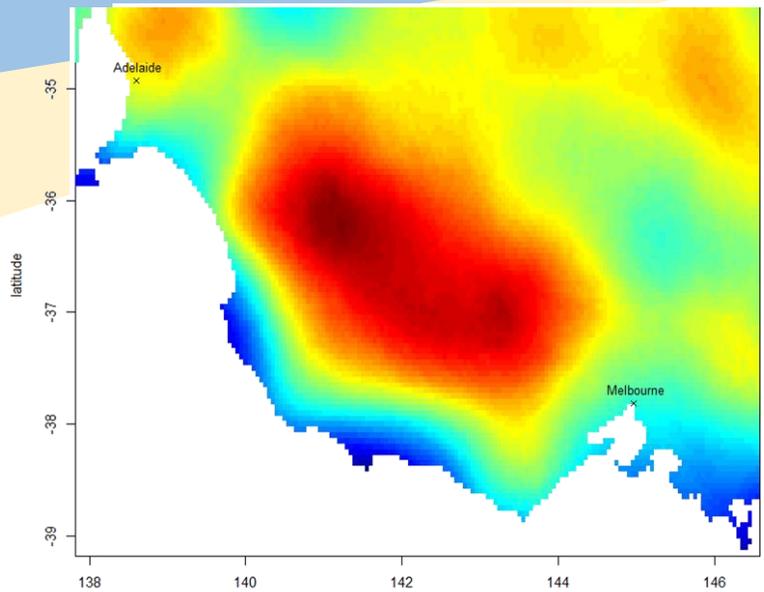

2009-02-07 06:00:00 UTC - 2009-02-07 17:00:00 AEST

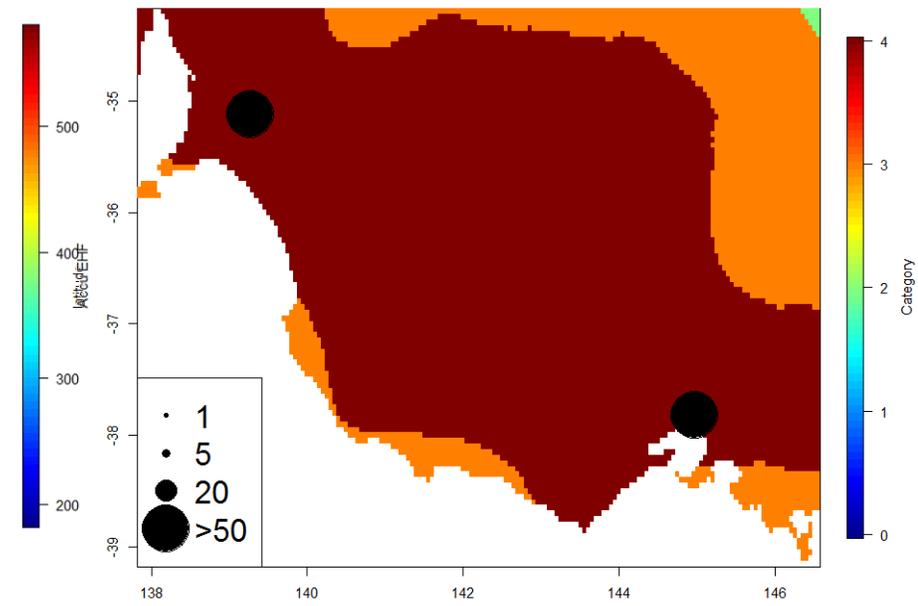

### Peak EHF over the event (2009)

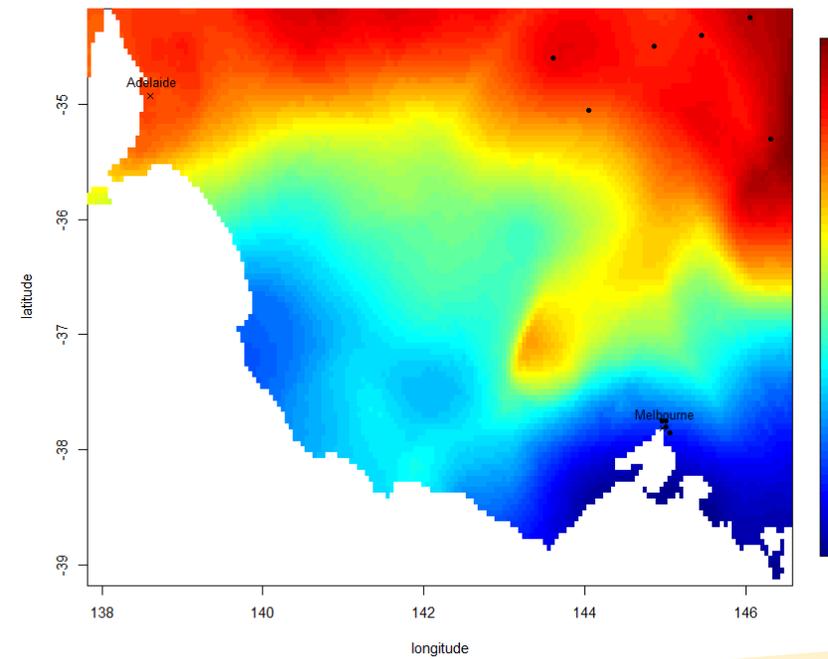

### EHF accumulation over the event

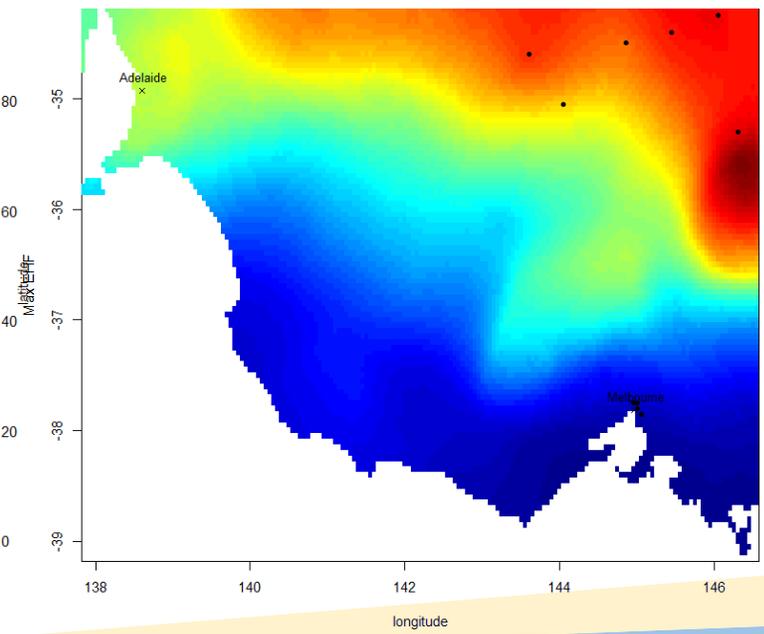

### Fatality risk categories (2009)

### Peak EHF over the event (1939)

### EHF accumulation over the event

### Fatality risk categories (1939)
